Summary of Defects Among Men Drafted in the World War New Pneumococcus Crossing With Five Recognized Strains

FEDERAL SECURITY AGENCY

UNITED STATES PUBLIC HEALTH SERVICE

THOMAS PARRAN, Surgeon General

DIVISION OF SANITARY REPORTS AND STATISTICS

CHARLES V. AKIN, Assistant Surgeon General, Chief of Division

The Public Health Reports, first published in 1878 under authority of an act of Congress of April 29 of that year, is issued weekly by the United States Public Health Service through the Division of Sanitary Reports and Statistics, pursuant to the following authority of law: United States Code, title 42, sections 7, 30, 93; title 44, section 220.

It contains (1) current information regarding the prevalence and geographic distribution of communicable diseases in the United States, insofar as data are obtainable, and of cholera, plague, smallpox, typhus fever, yellow fever, and other important communicable diseases throughout the world; (2) articles relating to the cause, prevention, and control of disease; (3) other pertinent information regarding sanitation and the conservation of the public health.

The Public Health Reports is published primarily for distribution, in accordance with the law, to health officers, members of boards or departments of health, and other persons directly or indirectly engaged in public health work. Articles of special interest are issued as reprints or as supplements, in which forms they are made available for more economical and general distribution.

Requests for and communications regarding the Public Health Reports, reprints, or supplements should be addressed to the Surgeon General, United States Public Health Service, Washington, D. C. Subscribers should remit direct to the Superintendent of Documents, Washington, D. C.

Librarians and others should preserve their copies for binding, as the Public Health Service is unable to supply the general demand for bound copies. Indexes will be supplied upon request.

SUMMARY OF PHYSICAL FINDINGS ON MEN DRAFTED IN THE WORLD WAR

By Rollo H. Britten, Senior Statistician, and George St. J. Perrott, Chief, Division of Public Health Methods, National Institute of Health, United States Public Health Service

In connection with a suggested program of physical rehabilitation of registrants disqualified for duty with the armed forces under the Selective Training and Service Act of 1940,¹ it is desirable to summarize in available form the major findings of the World War draft examinations of 1917–18.² On the basis of estimates of the number of men to be conscripted in the draft of 1940–41,³ the World War draft findings afford some indication of the numbers of men who, because of physical and mental impairments, will be classified as not available for general military training in the various States between now and July 1, 1941, and also the impairments which will be recorded among them.

¹ See Public Health in the National Defense Program. Summary of Proceedings, Special Conference of State and Territorial Health Officers with the United States Public Health Service, Washington, D. C., September 16-17, 1940. Pub. Health Rep., 55: 1760-1776 (1940).

² Love, Albert G., and Davenport, Charles B.: Defects Found in Drafted Men. Statistical information compiled from the draft records, showing the physical conditions of the men registered and examined in pursuance of the requirements of the Selective Service Act. Government Printing Office, Washington, 1920.

³ Preliminary quotas by States announced by the Selective Service headquarters (October 19, 1940) are as follows:

First Corps Area 37, 961	Fourth Corps Area-Con.	Seventh Corps Area-Con.
Connecticut 8, 421	Louisiana 15, 084	North Dakota 3, 401
Maine 3, 081	Mississippi 12, 759	South Dakota 3, 525
Massachusetts 20,556	North Carolina. 15, 613	Eighth Corps Area 52, 475
New Hamp-	South Carolino. 5, 957	Arizona 3, 098
shire 1,579	Tennessee 14, 229	Colorado 3, 837
Rhode Island 3, 118	Fifth Corps Area 91, 192	New Mexico 2, 962
Vermont 1, 208	Indiana 21, 087	Oklahoma 9, 365
Second Corps Area 148, 295	Kentucky 9, 154	Texas 33, 213
Delaware 1, 329	Ohio 52, 497	Ninth Corps Area 54, 985
New Jersey 32, 170	West Virginia 8, 454	California 38, 017
New York 114, 796	Sixth Corps Area 131, 137	Idaho 1, 954
Third Corps Area 87, 815	Illinois 62, 223	Montana 2, 563
District of Co-	Michigan 47, 282	Nevada 624
lumbia 3, 982	Wisconsin 21, 632	Oregon 2, 806
Maryland 12, 564	Seventh Corps Area. 84, 625	Utah 2, 153
Pennsylvania 61,522	Arkansas 8, 846	Washington 5, 821
Virginia 9, 747	Iowa 11, 738	Wyoming* 1,047
Fourth Corps Area 100, 515	Kansas 8, 388	Hawaii 1, 400
Alabama 13, 711	Minnesota 18, 652	Puerto Rico 9, 600
Florida 10, 370	Missouri 23, 619	
Georgia 12, 792	Nebraska 6, 456	Total 800, 000

•Wyoming was subsequently changed from the Ninth to the Seventh Corps Area.

In order that the data given may be as valuable as possible from this point of view, the present summary has been confined to a group of drafted men (the so-called "second million") who were examined at camp after May 1, 1918. By this time, examination procedures had become more efficient and standardized, and, it is believed, more nearly comparable to those which will be given under the present law.⁴ It is necessary, of course, to consider the local board examinations also, since men rejected (and a large proportion of those placed in limited service groups) by local boards were not sent to camp and were therefore not included in the camp records.⁵ Local board data are, in general, limited to the reexaminations made under an order promulgated by the President on November 8, 1917.

On this basis 21.3 percent of drafted men ⁶ were rejected, 9.9 percent were placed in limited service groups, and 52.1 percent were found to have defects. Thus, about one-third (31.2 percent) were classified as not available for general military service. If one felt justified in applying this latter percentage to examinations to be made under the Selective Training and Service Act of 1940, he would conclude that about 1,200,000 men would have to be examined to meet the quota of 800,000 (expected by July 1, 1941) and thus that about 400,000 would be rejected or placed in the limited service group, i. e., would be classified, on physical grounds, as not available for general military

service.7

On the basis of World War draft data to be given later in this paper estimates may be made of the number of defects which will be noted among these 400,000 men. Such estimates are presented (to the nearest hundred) in table 1. It is to be observed that a single individual might have been recorded as having more than one impairment, which explains the fact that the number of impairments is 497,100 and not 400,000. Figures 1 and 2 present the comparison graphically, first by broad groups of defects, second by more specific defects. In the charts, rates (taken from table 4) are substituted for the actual numbers, since they are more generally applicable. It would be desirable, but is not practicable, to give the proportion of persons according to the defect which caused them to be judged unfit for general military service; however, rates are calculated per 1,000 total drafted men rather than per 1,000 men not available for general military service, in order to come as close as possible to this concept.

⁴ An additional point is that the punched cards for the so-called "first million" recorded only one defect on any one individual, whereas the cards for local board examinations and for the "second million" recorded more than one (if reported).

⁵ See appendix for method of calculation. Rates given on pp. 1763–1764 of the article cited in footnote 1 differ from those appearing in this report by reason of differences in the method of calculation. In the former article, for instance, persons placed in limited service groups by local boards (and who did not get to camp) were disregarded.

On The term "drafted men," as used in this report, refers to examined persons, thus including those rejected.
Number to be examined equals quota (800,000) divided by 1 minus the proportion classified as not available for general military service (taken as one-third because of lack of precision in the estimate).

Table 1.—Estimated number of defects that will be found among 400,000 men not available for general military service because of physical or mental impairments (out of a total of 1,200,000 men examined)

Diseases or defects	Nu	nber	Diseases or defects	Nun	nber
Orthopedic impairments Crippled or paralyzed members Lost members: Upper extremities: Fingers Other Lower extremities Flat feet Other specified foot defects Curvature of the spine Eye defects Defective vision Blindness in one or both eyes Trachoma Other eye defects Cardiovascular-renal diseases Valvular diseases of the heart Cardiae hypertrophy Tachycardia Functional heart diseases Underweight Hernia and ingulnal rings Hernia Enlarged rings	56, 700 35, 600 31, 000	46, 400 6, 300 1, 800 4, 700 38, 900 20, 800 7, 500 49, 000 8, 800 1, 300 5, 100 33, 400 4, 600 5, 800 8, 800 1, 100 8, 800	Tuberculosis (all forms) actual or suspected. Defective and deficient teeth. Nervous or mental diseases. Mental deficiency Epilepsy Mental alienation. Other. Ear defects Defective hearing Otitis media. Other ear diseases. Veneral diseases. Gonorrhea. Syphilis. Chancroid. Varieose veins, varieocele. Goiter. Hypertrophic tonsillitis Arthritis and allied affections. Asthma. Other diseases or defects. All diseases or defects.	28, 600 17, 500 8, 500 7, 400 6, 800 6, 300 3, 800 2, 700	14, 400 4, 700 4, 400 5, 100 8, 200 8, 200 1, 100 5, 000 3, 300 200

It will be observed that many of the diagnosis groups represent defects of which a large proportion may be regarded as remediable. From this point of view, perhaps the most important conditions are: Defective vision (40.8 per 1,000 total drafted men), underweight

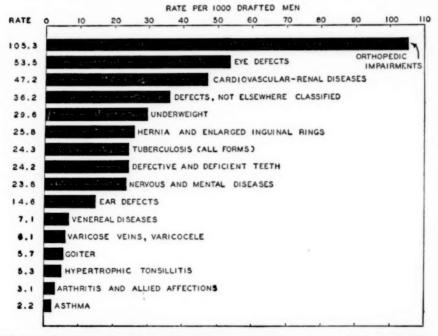

FIGURE 1.—Prevalence of defects (per 1,000 drafted men) noted in men who were rejected or accepted for limited service only (broad groups).

(29.6), tuberculosis (24.3), defective and deficient teeth (24.2), hernia (21.0), venereal diseases (7.1),⁸ defective hearing (6.8), otitis media (6.8), varicose veins and varicocele (6.1), goiter (5.7), hypertrophic tonsillitis (5.3), and trachoma (1.1). Many of the individual cases classified under various other diagnosis groups would also prove to be correctible.

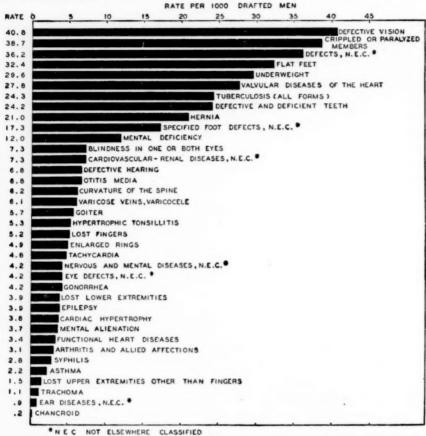

FIGURE 2.—Prevalence of defects (per 1,000 drafted men) noted in men who were rejected or accepted for limited service only (specific diagnoses).

The possible distribution, by States, of the estimated 400,000 men not available for general military training is, of course, of great interest as indicating the extent of the problem of rehabilitation in each State. Any such figures are subject to grave errors, since the number who will volunteer in each State is not known, and since it is not certain to what extent the wide State-to-State variation of the World War draft data will be repeated in the present examinations, but there seems no basis upon which any estimates can be made other

In view of modern serodiagnostic methods and the adoption of plans for Wassermann tests on all persons examined, the number of men diagnosed as having venereal disease may be expected to be increased considerably.

than the experience of the World War draft. Hence, in spite of a possible early refutation of the estimates, they are presented here as the only available estimates of the magnitude of the proposed rehabilitation project in each State. The numbers are given in table 2 and the percentages in figure 3.

Table 2.—Estimated distribution by State of 400,000 persons not available for general military service 1

State	Estimated number	State	Estimated number
Alabama	4,600	Nevada New Hampshire	200 1, 000
Arkansas	2, 600	New Jersey	17, 200
California	22, 100	New Mexico	1, 100
Colorado	2, 300	New York	78, 500
Connecticut	4, 800	North Carolina	6, 900
Delaware	800	North Dakota	1,000
District of Columbia	1,800	Ohio.	22, 400
Florida	4, 400	Oklahoma	3, 100
Georgia	5, 900	Oregon	1, 700
Idaho	800	Pennsylvania	33, 700
Illinois	28, 100	Rhode Island	4,600
Indiana	7,800	South Carolina	2,600
Iowa	4, 700	South Dakota	1,300
Kansas	2, 400	Tennessee	7, 200
Kentucky	3, 300	Texas	9, 900
Louisiana	6,900	Utah	1, 100
Maine	2,900	Vermont	1,500
Maryland	6, 900	Virginia	5, 500
Massachusetts	17, 100	Washington	4, 200
Michigan	27,000	West Virginia	3,000
Minnesota	6, 900	Wisconsin	9, 700
Mississippi	4, 700	Wyoming	200
Missouri	10, 100		
Montana	900	All States	400,000
Nebraska	1, 700		

¹ The estimate is exclusive of Alaska, Hawaii, and Puerto Rico.

It will be observed that the rates vary widely by State. For Rhode Island the rate (of persons classified as not available for general military service) was 58.5 percent; for Wyoming, at the other extreme, it was 18.4. For a discussion of the significance of the variation from State to State it will be necessary to consult the report, "Defects Found in Drafted Men." It is manifest, however, that part of the variation is to be ascribed to real differences in the physical condition of men coming from different States, part to variations in the examination technique of local boards, and part to similar variations at the camps.

It is not practicable to say to what extent the differences among States in 1917–18 will be reflected in the new draft examinations. Insofar as the variation represents real geographic differences in physical status, it is plausible to expect a recurrence of the same phenomenon. Insofar as it represents a different average level of examination technique of local boards in different States, we may perhaps expect more or less conformity to the same pattern. Much of the variation by camps, however, must be regarded as dependent on a complicated set of circumstances, involving camp management as well as the proficiency of the medical staff.

DESCRIPTION OF DATA USED

The figures used for the number of men examined by the local boards are as given in the report, "Defects Found in Drafted Men." They comprise: (a) Men examined by local boards after December 15, 1917 (3,247,888), and (b) 516,212 men who had entrained for

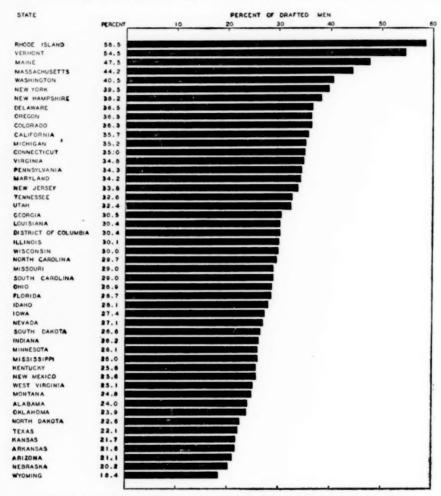

FIGURE 3.—Percentage of drafted men rejected or accepted for limited service only, by State.

I

Io

K L M M M M M M M M M

camps in the first draft, prior to December 15. Most of the men were between the ages of 21 and 31. The figures on the number rejected by the local boards (549,099 for the whole country) are again those given in the report, "Defects Found in Drafted Men." Figures for the number of men placed in limited service groups by the local boards were obtained from a report of the Provost Marshal General.

^{*}Second Report of the Provost Marshal General to the Secretary of War on the Operations of the Selective Service System to December 20, 1918. Government Printing Office, Washington, 1919.

There were 427,813 such men, of whom 128,355 reached camp (by September 11, 1918).

The "second million" constituted a sample of 967,486 men out of 1,672,661 sent to camp after May 1, 1918 (excluding third registration, which extended the age limits to 18 to 45, and certain special groups). The sample for which data are shown in the report, "Defects Found in Drafted Men," was obtained by taking physical examination records from an alphabetical file beginning with the letter A and continuing through the letter N. As indicated, 994,206 camp examinations made prior to May 1, 1918 ("first million") are disregarded in the present summary.

All figures relate to white and colored persons combined. Methods of calculation are described in the appendix.

DISCUSSION OF DETAILED TABLES

Table 3 gives the number of persons, by States, (a) examined and rejected by the local boards, or (b) falling into different physical status groups on the basis of camp examinations. In the succeeding tables the results of the local board and camp examinations are combined as described in the appendix.

Table 3.—Number of men examined by local boards and at camp ("second million") according to physical status groups

As stated above, it was not possible to give data with respect to the number of men rejected for, or placed in limited service groups by reason of, specific defects. No classification was made in the draft report by men according to cause. In fact, more than one cause was frequently associated with the rejection or classification into limited service groups. The rates will therefore be given per 1,000 drafted men, but the impairments will be subdivided on the basis of the physical status group into which the men themselves were placed. The rates are shown in table 4 by diagnosis.10

¹⁰ The draft diagnosis classification numbers (see table 5) of the conditions included under each of the categories listed in table 4 are as follows:

Orthopedic impairments:	Eye defects—Continued.	Nervous or mental diseases - Con.
Crippled or paralyzed mem-	Other eye defects (78-80,	Epilepsy (46, 47).

Asthma	2. 06 27, 12		2. 23 36. 24		2.33	
Other diseases or defects	27.12		30. 24		53. 56	
All diseases or defects	276. 83		414.05		661.94	

The three physical status groups employed are: (a) Rejected men; (b) men not accepted for general military service (i. e., rejected men plus those placed in limited service groups); and (c) total with some recorded defect (i. e., rejected men, plus those accepted for limited service, or accepted for general military service with recorded defect). The second of these groups, (b), was utilized as a basis for the estimated numbers in table 1.

The three groups are presented separately to give as adequate a statement as possible of the rate of defects of varying degrees of severity likely to be encountered in the present conscription examina-

¹¹ The rates in table 4 are additive, those for the limited service groups being obtainable by subtraction of the first two columns from the third and fourth, respectively; those for the group accepted for general military service are obtainable by subtracting the third and fourth columns from the fifth and sixth, respectively.

tions; but, as indicated previously, the second concept is perhaps of chief interest—the rate of defects (per 1,000 total drafted men) noted among persons who were not qualified for general military service.

As a basis for more intensive study, in table 5 the rates are given according to the detailed diagnosis list of the draft report. To save space the table is limited to men who were not available for general military service.

Table 5.—Prevalence of defects noted in men who were rejected or accepted for limited service only. Detailed diagnosis list

Wisconsin	19.9	30.0	54.4	Wyeming	12.6	18.4	56. 8

Causes of the wide variation in the rates from State to State have already been discussed. It will be noted that this tendency is present in each of the three groups of defects.

In table 7 the data by diagnosis are presented for each State, again employing, for brevity, the rate (per 1,000 total drafted men) of defects noted in men who were not available for general military service.

Table 7.—Prevalence of defects (per 1,000 total drafted men) noted in men who were rejected or accepted for limited service, by State

From earlier discussions in this article, it is apparent that much uncertainty attaches to the question of the number of defects which will be noted, State by State, among persons classified as not available for general military service under the administration of the present conscription law. But, although it is not clear to what extent the findings of the 1917–18 draft in each State will be repeated in the present instance, it is equally clear that there is no other basis on which to make reasonable estimates. National estimates were given at the beginning of the article. If a person desires to make similar estimates by impairments for individual States, he can do so from table 7, providing the number of men to be examined in the given State is known. The procedure would be to multiply this number of men to be examined by the rates for each diagnosis group for that State (dividing by 1,000 to place the calculation on a per person basis).¹²

¹² If it is desired to make the calculation from the quotas of men to be inducted (as, for example, those given in footnote 3), the procedure would be to divide the quota by 1 minus the proportion of men classified as not available for general military service (expressed per person, i. e., figures from table 6 for the given State divided by 100). The quotient is then the estimated number of examinations necessary to produce the quota.

By way of example, the New York quota (footnote 3) is 114,796. Table 6 gives, for that State, 39.5 as the percentage not available for general military service. Hence, the estimated number to be examined would be 114,796 divided by 1 minus 0.395, or 189,620.

SUMMARY

1. In connection with a suggested program of physical rehabilitation of registrants disqualified for general military service under the conscription act of 1940, the medical findings of the World War draft of 1917–18 ("second million") have been summarized.

2. Twenty-one percent were rejected for military service, 31 percent were classified as not available for general military service (including the rejections), and 52 percent had one or more recorded defects.

3. On the basis of the World War draft of 1917–18, one might expect that, to meet the quota of 800,000 inducted men by July 1, 1941, 1,200,000 would have to be examined and thus that about 400,000 would not be available for general military service.

4. On the same basis, the estimated number of defects to be found among these 400,000 persons is given, the most frequently occurring conditions which are largely remediable being defective vision, underweight, tuberculosis, defective and deficient teeth, hernia, and venereal diseases.

5. Again on the same basis, estimated numbers of persons in each State who will be classified as not available for general military service are also given, with the percentages. There is wide variation from State to State in the percentages.

6. Data are presented to permit estimates of the number of defects of different kinds which will be found among persons examined in each State.

APPENDIX

SECTION A

Calculation of percentage of persons placed in each physical status group

As specified in the text, this analysis is confined to "second million" (plus local board) examinations. The method of combining these two sources of information is most easily explained by indicating the precise calculations, as done in table 8.

Table 8.—Calculation of percentage of persons placed in physical status groups

Item	Line	Number
LOCAL BOARDS		
Number of local board examinations a	1	3, 764, 10
Number of rejections by local boards a	2 3	549, 09
Number placed in limited service groups b s.	3	427, 813
Number placed in limited service groups b s. Number who did not reach camp ("DNRC") b s.	4	299, 458
Number who did reach camp ("RC")	5	128, 35
Number rejected at camp b	6	16, 48
Number in "second million"	7	74, 24
Estimated distribution at camp:		
General service (with defects) /	8	23, 24
Limited service	8	41, 46
Rejected A	10	9, 53
Total number rejected or placed in limited service groups '	11	976, 913
Difference between this number and number examined i	12	2, 787, 189

• The "remediable" group has been combined with the "limited service" group, since men were transferred from the former to the latter before being sent to camp. Only a nominal number of persons were placed in the "remediable" group at the camps.

4 "DNRC" is used in this explanation for the group of persons who were placed in limited service groups by local boards, but who did not reach camp (by Sept. 11, 1918); "RC" is used for those so classified who did

reach camp.

'Line 5 times $\frac{\text{line 14}}{\text{line 15}}$. Only a few persons from limited service groups reached camp soon enough to be included in the "first million"; hence, the estimated number to be found in the "second million" depends on the proportion which the "second million" was of the sample from which it was drawn.

'Line 7 minus the sum of lines 9 and 10.

From line 19. All persons classified at camp as limited service are assumed to have been so classified by local boards.

By way of explanation, it should be stated that examination records of persons placed in limited service groups by local boards were not available for the analyses covered in the report, "Defects Found in Drafted Men." Of this group, those who later reached camp were reexamined there and their records are included, if they were in the "second million"; however, only part of the limited service group ever got to camp. Those who did, did not do so early enough to be included, in any numbers, in the "first million." Hence, they form a disproportionate part of the "second million" and require a factor to "step up" the records to the full universe of discourse (i. e., local board examinations).

Calculations of the rates of defects followed the methods described in section A, the number of cases found at camp for any one defect being "stepped up" to the full universe of discourse just as the persons among whom these cases occurred had been "stepped up."

In view of the fact, however, that no information as to diagnosis was available for men who had been placed in limited service groups by local boards, a further assumption was necessary. It was that the relative distribution of different impairments in the limited service groups as found at camp could be taken to represent the relative distribution at the local boards.

The complete calculation is shown in table 9 for one defect (hernia).

Table 9.—Calculation of rates of hernia (per 1,000 drafted men) among persons classified by physical status. (Hernia used as an example of the procedure)

Line 4 times 2.9651. This factor, applicable to each diagnosis, equals the following (from table 8):

$$\left(\frac{\text{line } 24}{\text{line } 20} \times \frac{\text{line } 12}{\text{line } 25}\right) + \left(\frac{\text{line } 10}{\text{line } 20} \times \frac{\text{line } 15}{\text{line } 14}\right)$$

/ Line 5 times 8.9510. This factor, applicable to each diagnosis, covers the "DNRC" group and also persons classified as available for limited service at camp. It is equal to the following (from table 8):

$$\frac{\text{line 4}}{\text{line 9}} + \frac{\text{line 15}}{\text{line 14}}$$

Line 6 times 2.9973. This factor, applicable to each diagnosis, equals the following from table 8:

$$\left(\frac{\text{line } 22}{\text{line } 18} \times \frac{\text{line } 12}{\text{line } 25}\right) + \left(\frac{\text{line } 8}{\text{line } 18} \times \frac{\text{line } 15}{\text{line } 14}\right)$$

SECTION C

Calculations by States

Since, for each State, information was not available as to the proportion who reached camp out of those who were placed in limited service groups by local boards, the national proportions were necessarily used in arriving at the percentage of persons placed in the different physical status groups in each State (table 6.)13

¹³ The value, for any State, corresponding to that given on line 28 of table 8 was obtained by multiplying the number placed in limited service groups by local beards in the given State by $\frac{10,105}{427,813}$

The value, for any State, corresponding to that given on line 27 of table 8 was obtained by (a) multiplying 967,486 the above product by $\frac{307,780}{1,672,661}$, (b) subtracting the result from the number rejected at camp for the given State, and finally (c) multiplying the difference by a separate factor for each State. This factor has for its numerator the value, for the given State, corresponding to line 12 of table 8, and for its denominator the difference between (1) the number examined at camp ("second million") in the given State and (2) the number placed in limited service groups by local boards times $\frac{128,355}{427,813}$ times $\frac{967,486}{1,672,661}$

The value, for any State, corresponding to that given on line 31 of table 8 was obtained by multiplying the number who were placed in limited service groups by local boards in each State by $\frac{200,100}{427,813}$

The value, for any State, corresponding to that given on line 32 of table 8 was obtained by multiplying the number placed in limited service groups at camp in the given State by $\frac{1,672,661}{967,486}$

The value, for any State, corresponding to that given on line 36 of table 8 was obtained by subtracting the calculated value corresponding to line 32 from the product of (a) the number of persons placed inlimited service groups by local boards in the given State and (b) the factor $\frac{111,867}{427,813}$ (i. e., $\frac{128,355-16,488}{427,813}$)

The value, for any State, corresponding to that given on line 35 of table 8 was obtained by (a) multiplying the calculated value corresponding to line 36 by $\frac{301,733}{1,672,661}$, (b) subtracting the product from the number of persons found at camp to be available for general military service, with defects, and (c) finally multiplying this difference by the factor mentioned in connection with the calculation for line 27.

In the calculation of table 7, the factor given in footnote e of table 9 was used without change, as a convenient approximation. However, the factor given in footnote f of table 9 was modified by substituting, for the first term, the product of (a) $\frac{299,458}{427,813}$ and (b) the quotient obtained by dividing the number of men placed in limited service groups by local boards in the given State by the number placed in limited service groups at camp for the given State.

REPORT OF A NEW TYPE OF PNEUMOCOCCUS WHICH CROSSES WITH TYPES X, XI, XX, XXIX, AND XXXI ANTIPNEUMOCOCCIC SERUMS¹

By Alice L. Chinn, Junior Bacteriologist, and Bernice E. Eddy, Associate Bacteriologist, United States Public Health Service

During the pneumococcus type incidence survey conducted recently in northern California by the United States Public Health Service in cooperation with the California State Department of Public Health, it was observed that certain pneumococci reacted with more than one type-specific serum. In this survey, which covered 23 counties in northern California, one or more specimens of sputum, other biological fluids, or cultures, from 1,096 patients were examined at the State public health laboratory at Berkeley to determine the presence of significant organisms, and to type pneumococci whenever these were present. Most of the patients were proved cases of pneumonia. Specimens from 255 cases were sent to the State laboratory for a primary diagnosis. The specimens from 841 cases had already been examined by a hospital or private clinical laboratory and were brought to the State laboratory by messenger for checking or further study. This phase of the survey covered the period from January 20, 1939, to April 30, 1940.

The method used for examining the sputums, other biological fluids, or cultures, was as follows: The specimen was examined by the Neufeld method to determine the presence and type of pneumococcus. If no swollen capsules were observed the material was injected intraperitoneally into a white mouse and/or a blood agar plate was streaked, or dextrose blood broth or dextrose ascites broth was inoculated with

the material being tested.

The technique of the Neufeld test was that described by Walter (5). A small (1 mm.) loopful of the specimen was placed on a flat glass slide and a large (4 mm.) loopful of serum and a large loopful of Loeffler's methylene blue were mixed with it. A coverslip was

placed over the mixture at once. The preparation was examined under the oil immersion lens with a strong light partially dimmed.

All specimens were tested with each of the diagnostic group serum mixtures, and then with each specific type serum included in any group mixture which caused capsular swelling or agglutination of the pneumococci. In the case of specimens in which specific types had been reported by the hospital or private laboratory which submitted the specimen, if the group serum mixture containing a reported type caused no capsular swelling or agglutination, the organism was tested with the specific serum of the type reported.

The mice were inoculated intraperitoneally with 0.25 cc. to 0.5 cc. of sputum or culture. If the mice survived 12 to 24 hours after inoculation, but were moribund, they were killed. Otherwise, they were allowed to live for 5 or 6 days before they were sacrificed. From a few such mice which had never shown signs of illness, positive brain and heart blood cultures were obtained. Peritoneal punctures were not routinely made.

Following the death of a mouse, Neufeld tests were performed on the peritoneal fluid, and cultures were made from the peritoneal fluid, heart blood, and brain. The peritoneal fluid was streaked over a blood agar plate and the heart blood and brain were cultured in broth enriched with either blood or ascites fluid. If growth was obtained, the cultures were tested by the Neufeld method.

The media were prepared according to the methods described by Walter (5). Horse blood was used for the blood agar plates. A 20-percent solution of dextrose was added to the broth in amounts sufficient to make 0.5 percent. Either horse blood or ascites fluid was used for further enrichment. These seemed equally effective.

The first multiple reaction observed was one in which the organisms exhibited swollen capsules with both type XX and type XXIX serums. This reaction was obtained both by a Neufeld test performed directly on the sputum and with organisms obtained from a blood agar plate which had been streaked with the sputum.

Later, other specimens were encountered which reacted with two or more of the diagnostic antipneumococcic serums, types X, XX, XXIX, and XXXI. In every case the possibility of the mixture of these types was excluded. Only one specimen was recorded as reacting with types X, XI, XX, XXIX, and XXXI. At the time, this specimen was believed to contain a type XI pneumococcus in addition to the multiple reacting pneumococcus.

Most of the multiple reacting pneumococci were noted in direct examination of sputum. During the last 2 months of the survey, whenever reactions with one of the types X, XX, XXIX, or XXXI serums occurred, each specimen in which one of these types was found was also examined for the remaining three types. The number

of specimens containing pneumococci which reacted with these types is given in table 1.

Table 1.—Cases from which were obtained specimens 1 containing pneumococci which reacted with more than I type-specific serum

Types found 2	Number of cases	Types found 2	Number of cases
X, XXIX XX, XXIX XX, XXXI	6 4 3	X, XX, XXXI X, XX, XXIX, XXXI X, XI, XX, XXIX, XXXI	4 7 1
XXIX, XXXI X, XX, XXIX	7	Total	33

¹ The 33 original specimens, obtained from the same number of cases, consisted of 29 sputums, 2 throat cultures, 1 lung puncture fluid, and 1 blood culture.

² In 28 of the 33 cases these types were found in the original specimen by the Neufeld technique. In the remaining 5 cases the pneumococci were demonstrated only by mouse inoculation or in broth culture or

The 4 types were also found singly in specimens. Type X alone was present in 12 specimens, type XX in 23, type XXIX in 7, and type XXXI in 14. In addition, one of these 4 types was found in combination with one or more other types in 20 specimens.

The incidence of these types and the multiple reacting type which we have listed as "odd" is given in table 2. It will be noted that the incidence of the multiple reacting pneumococci (4.2 percent of all types and 4.9 percent of the higher types) exceeds any one of the four types in the survey in California.

1 Whenever any one type was designated as predominating it is placed first and separated from the others by a comma. When no type seemed to predominate, the types are separated by a dash.

In cases Nos. 1 to 7, inclusive, the findings were confirmed by blood agar plates.

The recorded findings for each of cases Nos. 16 and 25 are the composite of the findings in two specimens.

A careful study of these pneumococci was not undertaken until late in the pneumococcus type survey. The first strains of multiple reacting pneumococci had not been kept. However, 2 strains of these pneumococci were isolated from the throats of 2 convalescent patients who had previously harbored pneumococci reacting with 4 type-specific serums, and 4 similar strains were isolated from new cases. A study of 5 of these strains forms the basis for our conclusions that the 5 strains are identical and that they represent a distinct type of pneumococcus which differs from all of the 32 recognized types but which gives cross reactions with types X, XI, XX, XXIX, and XXXI serums. One of the 6 strains which had been preserved in a dry state while immunization experiments were being carried on failed to grow when needed.

HISTORY OF THE 6 STRAINS

Strain 18 was isolated from the throat of a white male patient, aged 61 years, who was convalescing from an attack of bronchopneumonia. At the time of the acute illness, in December 1939, a positive Neufeld reaction had been observed on examination of the sputum with serums of types X, XX, XXIX, and XXXI, and pneumococci which reacted with serums of these 4 types had been isolated from the sputum. No pneumococci were seen in a direct examination of a throat swab made 10 weeks later from the convalescing patient. Pneumococci, however, grew in a dextrose broth culture made from the throat swab. These pneumococci exhibited swollen capsules with type XXXI serum. After passage through a mouse, they reacted with types X, XX, and XXIX serums as well as with serum of type XXXI.

Strain 25 was isolated from the throat culture of a white male patient, aged 60 years, 6 weeks after recovering from bronchopneu-Pneumococci had been found reacting to serums of types X, XX, XXIX, and XXXI in a Neufeld test on sputum obtained at the time of the acute illness in January 1940, and also in a dextrose broth culture of the sputum. This culture had not been saved. throat culture was made in dextrose ascites broth. incubation, 2 mice were each inoculated with the culture. Pneumococci were not seen in the culture itself or on a blood agar plate streaked with the culture. The mice died, however, 24 hours after inoculation. An organism which was bile-soluble and which agglutinated with types X, XX, XXIX, and XXXI was isolated from each of the mice. Two mice were then inoculated with these cultures but they did not succumb. A subculture was made from one of the cultures obtained from the dead mice and mice inoculated with this culture died after 24 hours. The pneumococci isolated from these

mice and from subsequent mice through which the culture was passed reacted in different ways with the four type-specific serums. For example, some of the reactions were as follows: Swollen capsules with serums of types X, XXIX, and XXXI, and partially swollen capsules with type XX serum; swollen capsules with types X and XXIX, and agglutination with types XX and XXXI; swollen capsules with types X and XXIX, partially swollen capsules with type XXXI, and agglutination with type XX.

Strain 26 was recovered in January 1940 from sputum from a case of lobar pneumonia. The patient was a white man, aged 45. In a Neufeld test performed on the sputum, capsular swelling was produced by serums of types X, XX, XXIX, and XXXI. A mouse inoculated with the sputum did not succumb until the tenth day. Pneumococci were isolated from this mouse which at one time or another reacted with all 4 type-specific serums, types X, XX, XXIX, and XXXI.

Strain 30 was recovered from the sputum of a white woman, aged 34 years, who had bronchopneumonia. A Neufeld test performed on the sputum, which was obtained on the sixth day of illness, did not reveal the presence of a pneumococcus. However, a dextrose broth culture made from the sputum contained a pneumococcus whose capsules were swollen by serums of types X and XX. After one mouse passage, agglutination or capsular swelling was observed with serums of types X, XX, XXIX, and XXXI.

Strain 31 was from a case of lobar pneumonia in a white woman, aged 58. A Neufeld test performed on the sputum obtained on the third day of illness showed the presence of a pneumococcus with partially swollen capsules with type X serum. A dextrose broth culture made from the sputum and cultures from mice which had been inoculated with the sputum contained pneumococci which reacted with all four types of serum.

Strain 32 was isolated from fluid obtained from a draining sinus from the right lung of a white woman, aged 36, who was suspected of having tuberculosis. The patient had bronchopneumonia 5 years previously, following which she developed symptoms of tuberculosis. Many specimens of drainage fluid and sputum had been examined for tubercle bacilli at the State laboratories, but all were negative. One specimen contained a gram-positive diplococcus which proved to be a multiple reacting pneumococcus. This strain of pneumococcus, at the time the cultures were received at the National Institute of Health, appeared to have a slightly better capsule than any of the other five strains. For this reason it was chosen as the strain for producing immune serum in rabbits. After a few mouse passages, no differences in the size of the capsules of the different strains could be detected.

Virulence.—All of the six cultures were virulent for mice at the time of isolation, and, as a rule, the mice were dead 24 hours after inoculation. Exact tests for virulence were carried out on strains 18, 25, 30, 31, and 32 several months after the original isolations and after a number of mouse passages. These strains were highly virulent, as few as one pneumococcus being necessary to kill. As an example, the virulence test of strain 32 is given in table 4.

Table 4.—Virulence test of pneumococcus strain 32

¹ Survived.

The first questions to be answered regarding these multiple reacting pneumococci were: Are the strains immunologically identical? And do they belong to one of the four recognized types of pneumococci, types X, XX, XXIX, or XXXI, and only cross with the remaining three types?

For comparative purposes the test used at the National Institute of Health (4) for determining the potency of pneumococcus typing serums was used. It has been shown by one of us (B. E. E.) (1) that if the antigens are carefully prepared and standardized the results of these tests can be duplicated with reasonable accuracy. Tests were performed using antigens prepared from the homologous type pneumococci and from six strains of the multiple reacting pneumococci on diagnostic type-specific serums and upon concentrated rabbit serums prepared for therapeutic use by different commercial laboratories. The results are given in table 5. It will be observed that all six multiple reacting strains behaved in an identical fashion and that the extent of the cross reaction of the different commercial serums with the multiple reacting pneumococci depended largely upon the potency of the serum. There were exceptions, however, and these exceptions cannot at present be satisfactorily explained. They might be due to some difference in the type strain used for immunization or to some other variation of method of preparing the serum.

Agg. = Agglutination, no capsular swelling.

0=No capsular swelling or agglutination.

It is to be remembered that the results given in table 5 are quantitative Neufeld tests. The antigens were diluted to match as exactly as possible a turbidity standard containing 200 parts per million of silica. To 0.1 cc. of the standardized antigen not more than 0.1 cc. of serum was added. This fact, while it made comparisons of the extent of the cross reactions possible, may account for the failure of some of the diagnostic serums to react with the "odd" type, or to react with agglutination rather than capsular swelling. In the routine Neufeld test, more serum than culture is usually employed (5).

The number of lots of commercial diagnostic serums examined and the number which reacted with the "odd" type are given in table 6. It will be observed that type XXIX and type X serums most frequently crossed with the "odd" type, followed in order by serums of types XX, XXXI, and XI.

Table 6.—A summary of the results of tests of commercial diagnostic serums

Types of diagnostic antipneumococcic serums	Number of serums tested	Number of serums causing capsular swelling or complete agglutination of pneumococci of the "odd" type
X XI	11 16	8 2
XX XXIX	9 13 13	8
	13	13
XXXI	13	8

That the cross was greatest with types XXIX and X was again brought out when concentrated rabbit serums for therapeutic use were tested. The strongest type XXIX and type X serums gave titers of 1:8 and 1:4+, respectively, with the "odd" type. The strongest type XX, type XXXI, and type XI serums caused capsular swelling of the "odd" type but the titer for each serum was less than 1:4.

The relationship between the "odd" type and types X and XXIX, and possibly type XX, was again noted during the course of immunization of rabbits with the multiple reacting strain 32. (See table 7.) Serum obtained from the first preliminary bleeding had a capsular swelling titer of 1:2+ with strain 32, but caused no capsular swelling or agglutination of pneumococci of types X, XI, XX, XXIX, or XXXI. The serum from the second preliminary bleeding gave a titer of 1:8+ with the homologous strain and caused complete agglutination of type X pneumococci and partial agglutination of type XXIX pneumococci. The serum from the third bleeding gave a 1:16+ titer for strain 32 and caused complete agglutination of types X and XXIX pneumococci and partial agglutination of type XX pneumococci. As yet, the maximum titer of the serum of the rabbits under immunization remains 1:16+, and no capsular swelling of pneumococci of types X, XI, XX, XXIX, or XXXI has occurred.

Table 7.—Results of tests for cross reactions on serums of rabbits in the process of immunization with pneumococcus strain 32

Date of bleedings	Capsular swelling titer with	Tests for cross reactions with pneumococci—							
	homologous strain	Type X	Type XI	Type XX	Type XXIX	Type XXXI

0= No agglutination or capsular swelling. Agg.=Agglutination, no capsular swelling.

It may be noted in table 5 that there was a great discrepancy between the capsular swelling titers of the different commercial serums for the respective homologous types of pneumococci and for the multiple reacting strain or strains. This would suggest that the multiple reacting strains were not closely related to the five recognized types. To determine this point, cross absorption tests were made. Strong concentrated rabbit serums of each of the five types, X, XI, XX, XXIX, and XXXI, were absorbed with pneumococci of one of the multiple reacting strains, strain 32, and antipneumococci rabbit serum for strain 32 was absorbed with pneumococci types X, XX, and XXIX. The results are given in table 8. The titer of each of the

absorbed serums remained the same for the homologous type pneumococcus. Absorption of the commercial serums with strain 32 not only removed the antibody for this strain but for the multiple reacting strains 18, 25, 30, and 31 as well. An antipneumococcic rabbit serum for strain 32 was free of agglutinins for types X, XX, and XXIX after absorption.

DISCUSSION

This new type of pneumococcus is of interest from two standpoints. Its prevalence in the type incidence survey in California is greater than that of either types X, XX, XXIX, or XXXI, and its cross reactions with four and sometimes five of the present recognized types of serum increase the task of preparing specific pneumococcus typing serums.

It is interesting to compare the percentage of multiple reacting strains of pneumococci, 4.9 percent of the higher types in the California survey, with the figures given by Heffron (3) for types of pneumococci in and around Boston. The incidence of 20 of the recognized higher types of pneumococci among 2,961 strains in the Boston series was less than 4.9 percent each. The incidence for types X, XX, XXIX, and XXXI was 3.0, 3.1, 2.1, and 1.3 percent, respectively.

Whether the incidence of this new type is as great in other parts of the country as it was in California is as yet unknown. While work on these multiple reacting pneumococci was in progress, a report of four strains of pneumococci which reacted with maximal capsular swelling and agglutination with type XXIX serum and partial capsular swelling or agglutination with one or more of the serums of types X, XX, or XXXI, was made by Foster and Shaughnessy (2) in Illinois. No evidence was given to show that these strains do not belong to type XXIX. It is possible, however, that they are identical with our "odd" type.

Every lot of pneumococcus typing serum on the market is tested for cross reactions with all of the recognized heterologous types of pneumococci. In spite of this vigilance it is now evident that confusion with types X, XX, XXIX, XXXI and possibly type XI may occur when this new type is encountered.

Inasmuch as the reactions of the multiple reacting pneumococci with serums of types X, XI, XX, XXIX, and XXXI are only cross reactions and that the Neufeld reaction represents a quantitative combination of antigen and antibody (1) and thus varies with differences in the number of pneumococci as well as differences in the potency of the serums, it is not unusual that in different cultures, under different circumstances, the pneumococci sometimes showed capsular swelling. at other times only agglutination, and at still others no reaction of This variation in the reactions with the different specific serums as 6 of the multiple reacting strains were isolated and first passed through mice is given in table 9. Although the variation was great it is interesting to note that more positives were obtained with serums of types X and XXIX than with serums of types XXXI and Of the total Neufeld tests performed on the cultures or biological fluids, the preparations which contained pneumococci with completely swollen capsules were, respectively, 48 for type XXIX, 42 for type X, 24 for type XXXI, and 6 for type XX. This is, again, in line with the results of quantitative tests which showed that the greatest cross reactions were with types XXIX and X.

SUMMARY AND CONCLUSIONS

Thirty-three strains of pneumococci were observed to react with agglutination or swollen capsules with two or more of the diagnostic serums of types X, XX, XXIX, and XXXI.

The incidence of these multiple reacting strains in a survey in northern California during the period January 20, 1939, to April 30, 1940, was 4.2 percent of all types. This was a greater incidence than for any of the four types alone.

Five of the strains were carefully studied and evidence is presented showing that the five strains are immunologically identical, and that they represent a distinct type of pneumococcus which crosses not only with types X, XX, XXIX, and XXXI serums but with highly potent type XI serum as well.

COURT DECISION ON PUBLIC HEALTH

Ordinance regarding sanitary privies upheld.—(Alabama Court of Appeals; Lavender v. City of Tuscaloosa, 198 So. 459; decided August 6, 1940.) An ordinance of the city of Tuscaloosa provided that persons not having modern toilet facilities connected with the city sewerage system should build and maintain certain specified types of sanitary privies; that such privies should be cleaned by the city scavenger, for which service fees were to be collected by the city from the persons served; and that the failure or refusal to pay such fees when they became due and payable was a criminal offense. A person was convicted in the lower courts of violating this ordinance, the complaint charging the use of a privy upon which the fees for cleaning had not been paid as required by the ordinance.

On appeal to the court of appeals the appellant contended (1) that the ordinance was violative of the Federal Constitution in that it deprived him of the protection of the due process of law clause of the fourteenth amendment, (2) that the ordinance was violative of the Federal and State Constitutions because it failed to define sufficiently the standard of guilt, and (3) that the complaint was vague and indefinite in that it did not sufficiently inform the defendant of what he was called upon to defend or allow a reasonable joinder of issue thereon. With reference to these contentions the court was of the view that each of them was wholly without merit and said that it clearly appeared that the ordinance itself was a complete answer to, and a refutation of, them.

Another claim made by the appellant was that the ordinance violated the State constitution relative to a citizen's immunity from imprisonment for debt. Regarding this, however, the court said that the immunity from imprisonment for debt contemplated and provided in the constitution had application and was limited to debts arising out of contract and did not extend to and include a fine and costs imposed by the municipality for the willful neglect or refusal to comply with the public duty imposed upon the appellant by the terms of the ordinance upon which the prosecution was rested.

The judgment appealed from was affirmed.

PREVALENCE OF DISEASE

No health department, State or local, can effectively prevent or control disease without knowledge of when, where, and under what conditions cases are occurring

UNITED STATES

REPORTS FROM STATES FOR WEEK ENDED JANUARY 4, 1941

Summary

For the current week, 77,144 cases of influenza were reported in the United States as compared with 45,475 for the preceding week—the largest numerical increase since the beginning of the present epidemic. Some of these cases, however, may be delayed reports. The western and southern States reported the highest incidence of the disease, with Texas (32,983 cases), Kentucky (9,601), and Arkansas (6,516), recording the largest numbers of cases. Among the North Central groups of States, Kansas, with 2,453 cases (1,607 last week), reported the highest incidence.

The present epidemic of influenza first appeared on the West coast during the latter part of November of last year, and apparently has gradually extended eastward, principally along the southern tier of States, where the reported incidence has been preponderantly the highest. The New England and Middle Atlantic States have so far

remained relatively free from the disease.

)1

Influenza, measles, peliomyelitis, and whooping cough were above the 5-year (1935–39) median expectancy for the current week. The number of cases of poliomyelitis increased from 36 to 64, nearly half of which were reported in the Middle Atlantic and East North Central States (11 in New York, 7 in Ohio, and 17 in Wisconsin). No other States reported more than 3 cases.

One case of Rocky Mountain spotted fever was reported in Illinois, 3 cases of tularemia were reported in North Carolina, and 22 cases of endemic typhus fever were reported for the United States as a whole,

9 of which occurred in Georgia and 5 in North Carolina.

For the current week the Bureau of the Census reports 9,251 deaths in 88 major cities of the United States as compared with 8,939 for the preceding week and with a 3-year (1937–39) average of 9,280. As compared with the 3-year average, the influenza epidemic is not reflected in this urban mortality.

Telegraphic morbidity reports from State health officers for the week ended January 4, 1941, and comparison with corresponding week of 1940 and 5-year median

In these tables a zero indicates a definite report, while leaders imply that, although none were reported, cases may have occurred.

FOREIGN REPORTS

CANADA

Vital statistics—First quarter 1940.—The Bureau of Statistics of Canada has published the following preliminary statistics for the first quarter of 1940. The rates are computed on an annual basis. There were 19.7 live births per 1,000 population during the first quarter of 1940 as compared with 20.5 during the first quarter of 1939. The death rate was 9.9 per 1,000 population for the first quarter of 1940 and 11.0 for the same quarter of 1939. The infant mortality rate was 63 per 1,000 live births in this quarter as compared with 72 for the same quarter of 1939. The maternal death rate was 4.3 per 1,000 live births for the first quarter of 1940, and 4.4 for the same quarter of 1939.

The accompanying tables give the numbers of births, deaths, and marriages, by Provinces, for the first quarter of 1940 and deaths by causes in Canada for the first quarter of 1940 and the corresponding quarter of 1939.

Number of births, deaths, and marriages, first quarter, 1940

Province	Live births	Deaths (exclusive of still- births)	Deaths under 1 year of age	Maternal deaths	Marriages
